1 Introduction

According to the International Standards ISO 31-0:1992 to ISO 31-13:1992 (superseded by ISO 80000-2:2009), mathematical *constants* e, i, π should be typeset in roman (upright shape) and not in italic like variables (see [1] [2] [3] [4]). This package provides some tools to achieve this automatically.

Even though it is recommended to typeset vectors names in bold italic style [2] [4], they are often represented with arrows, especially in school documents or in physics. To draw nice arrows above vectors, we use the esvect package by Eddie Saudrais [5]. Additionally we provide a few more macros related to vectors with arrows, particularly to improve the typesetting of the norm: $\|\overrightarrow{AB}\|$ instead of the \mathbb{E}_{LX} version $\|\overrightarrow{AB}\|$, which is not vertically adjusted, or worse $\|\overrightarrow{AB}\|$ (when using $\left\| \text{Left...}\right\|$).

 $^{^*}$ This document corresponds to mismath v2.12, dated 2024/02/29. Thanks to François Bastouil for initial help in English translation.

The package also offers other macros for:

- · tensors,
- some common operator names,
- · a few useful aliases,
- enhancing spacing in mathematical formulas,
- · systems of equations and small matrices,
- displaymath in double columns for lengthy calculations.

To avoid compatibility issues, most of our macros will only be defined if there isn't already a command with the same name in the packages loaded before mismath. If a macro is already defined, a warning message will be displayed and the mismath definition will be ignored. If you wish to keep the mismath or the existing command, you can use \let\command\\relax, before loading mismath, or after.

 $[\langle options \rangle]$

The mismath package loads the amsmath package [6] without any options. If you want to use amsmath with specific options (refer to its documentation), you can include these options when calling mismath, or you can load amsmath with the desired options before loading mismath. When using the package unicode-math [7], mismath must be loaded before unicode-math, just like amsmath.

In addition mismath loads the mathtools package by Morten Høgholm and Lars Madsen [8]. This package offers numerous helpful macros and improvements of the amsmath package.

A recommendation, although rarely followed, is to typeset uppercase Greek letters in italic shape, similar to other variables [4]. This can be automatically achieved, for some particular fonts, with packages such as fixmath by Walter Schmidt [9], isomath by Günter Milde [10] or pm-isomath by Claudio Beccari [11] and optionally with many others (such as mathpazo or mathptmx with the option slantedGreek). However this feature is not implemented here due to a conflicting rule in France, where all capital letters in mathematics are required to be typeset in upright shape¹. When running through LualMTeX or XalMTeX you can also get this result by setting the option math-style=ISO in the unicode-math package.

2 Usage

2.1 Mathematical constants

\mathup

As for classic functions identifiers, *predefined* mathematical constants should be type-set in upright shape (typically in roman family), but this practice is not sufficiently respected, probably because it's a bit tedious. A first solution is to use the \mathup

¹The frenchmath package [25] ensures to follow the recommended French rules.

macro, which is preferable to \mathrm², for setting any group of letters in roman. For example you can use \mathup{e} to get the Euler's number.

To avoid cluttering a document that contains many occurrences of Euler's number (e) or imaginary numbers (i) with \mathup{e} or \mathup{i}, the package provides the \e command for Eulers number and \i or \j for imaginary numbers. Let us notice that \i and \j already exist in LaTeX. In LR (left-to-right) mode, they produce '1, J' without the dot, allowing you to place accents on them. However, in mathematical mode, they produce the warning "LaTeX Warning: Command \i invalid in math mode on input line \(\line \rangle \)". With the new definition provided by the package, \i and \j will be redefined specifically for mathematical mode.

\MathUp

\e

۱j

Indeed, typing a lot of backslashes for constants like e, i, or j in a document with numerous formulas can become tiresome. To alleviate this, the package proposes a powerful solution with the macro \MathUp{\char}\. For example, when \MathUp{e} is called, any subsequent occurrence of e will automatically be set in roman (upright shape), without the need to type \e explicitly. The effect of this macro can be either global or local, depending on whether it is used outside or inside an environment or braces. Furthermore, you can call this macro in the preamble to apply the change from the beginning of the document. This powerful feature allows you to bring a document up to the standards effortlessly. In fact, \MathUp can be applied to any valid single character, offering flexibility for various use cases (another use of it with probability will be presented in section 2.3).

\MathIt

When there are other occurrences of e, i or j as variables, you can still obtain italicized e, i or j using MTEX commands \mathit or \mathnormal, which are useful for a single use. However, you also have the option to use the inverse switch \MathIt{ $\langle char \rangle$ }, which has a global effect when used outside environments or braces, or a local effect when used inside them. Similar to \MathUp, \MathIt can be applied to any single character.

\MathNumbers \MathNormal

These macros enable you to set upright or normal (italic) typesetting for multiple letters in a single command. For instance, \MathNumbers{e,i} is equivalent to \MathUp{e}\MathUp{i}. In \MathNumbers, the comma separator between letters can be modified or removed as needed. In fact, this macro only affects the letters e, i, or j; it has no effect on other characters. On the other hand, \MathNormal can be utilized for probability as well (refer to section 2.3), and it accepts any comma-separated list of arguments. This means you can apply the normal italic math mode typesetting to various letters at once using \MathNormal.

 $\left[\left\langle option\right\rangle \right]$

The mathematical constant π should also be typeset in upright shape (see [1], [2], [4]), which is different from italicized π . However, this recommendation is even less commonly followed compared to the one concerning e and i [1]. The \pinumber com-

²The \mathup macro is based on \operatorfont, which comes from the amsopn package, automatically loaded by amsmath. In beamer, the default math font is sans serif, but \mathrm produces a font with serifs, which might not match the overall style of the presentation. Hence, using \mathup is indeed a better choice in beamer presentations to ensure that mathematical constants are typeset in upright shape and consistent with the default sans serif math font.

mand replaces the italic π with an upright π each time \pi is called. It functions in two different ways.

1. You can install a Greek letters package that provides the glyphs in upright shape. There are many available. Notably, let us mention upgreek [12], mathdesign [13], kpfonts [15], fourier [16] (used in the present document), libertinust1math, pxgreeks (using pxfonts), txgreeks (using txfonts)³, libgreek, etc. A special mention goes to lgrmath of Jean-François Burnol [17] which allows the use of any Greek LGR-encoded font in math mode. These packages provide commands like \uppi (upgreek), \piup (mathdesign, kpfonts, lgrmath), \otherpi (fourier), etc.⁴ In this case, \pinumber must be called in the preamble with the name of the command (without the backslash) giving access to the upright pi (piup, uppi,

command (without the backslash) giving access to the upright pi (piup, uppi, otherpi ...) as the argument for the optional parameter. However, installing such a Greek letters package will modify all the other Greek letter glyphs.

By using the preliminary code \MathNumbers{ei}\pinumber[otherpi] (assuming the fourier package is loaded) you can achieve the following result:

$$e^{i\pi} = -1$$
 yields $e^{i\pi} = -1$.

2. Without installing a package, it is possible to change only the glyph of pi without altering the original glyphs for the other Greek letters, which are typically in italics.

In this case, \pinumber must be called in the preamble with an optional argument of the key=value type. The key name corresponds to a package providing the same glyph. When a key is given without a value, \pinumber will choose a default value specified below (depending on the key). The following table summarizes the available options.

Option	Result	Option	Result
lgrmath=lmr	π	mathdes	ign π
lgrmath=Alegreya-LF	π	kpfonts	π
lgrmath=Cochineal-LF	π	fourier	π
lgrmath=		pxfonts	π
upgreek=Euler	π	txfonts	π
upgreek=Symbol	π		

 With the lgrmath key, we actually have numerous possibilities for values (any Greek letters math fonts in LGR encoding). The documentation of the lgrmath package explains how to check an visualize all available fonts on your distribution. We have only presented three of them. The default value is lmr.

³When using pxgreeks or txgreeks, they should be loaded *after* mismath to avoid an error due to conflict with the existing macros \iint, \iiint, \idotsint in amsmath.

⁴They have also options to typeset all the Greek lowercase letters in upright shape by default, but this in not our goal here.

- With the upgreek key, the default value is Symbol. There is a third possible value, Symbolsmallscale, which provides the same character as Symbol but reduced in size by 10 %.
- With the mathdesign key, there are actually 3 possible values: Utopia, Garamond, or Charter (default value), but the glyphs obtained for pi look very similar.
- With the kpfonts key, we have two possible values: normal (default) and light. The option kpfonts=light provides a slightly less bold character.
- The keys fourier (based on Utopia), pxfonts (based on Palatino) and txfonts (based on Times) are booleans whose default value is true (when called).
- When \pinumber is called without an argument in the preamble, it corresponds to the option lgrmath=lmr. This π character is particularly well-suited for use with the default Computer Modern or Latin Modern font family⁵.

The unicode-math package [7] provides \uppi, and you can use \pinumber [uppi] to produce automatic upright pi, but, with unicode-math, it can be quite complicated to make some other Greek letters packages work. In any case, such a package must be loaded after unicode-math and in \AtBeginDocument. However, unicodemath supports \pinumber very well with the previous key=value options, by calling \pinumber [option] after unicode-math.

\itpi

When you activate \pinumber, the original italic π is still accessible using \itpi.

\pinormal

In fact, \pinumber is a toggle, with its inverse toggle being \pinormal. The latter restores the \pi command to its default behavior. Thus, \pinumber can be used anywhere in the document (like \pinormal), but then without arguments and provided it has been initially called in the preamble, according to the procedures outlined above.

2.2 Vectors (and tensors)

/vec

By default, the \vect command⁶, produces vectors with arrows (thanks to the esvect package by Eddie Saudrais⁷) which are more elegant than those produced by Laren's \vectage has an optional argument (a single letter between a and h) to define the desired type of arrow (see [5]). In mismath, esvect is loaded with the option b: \vect{AB} gives \(\overline{AB}\) gives a different type of arrow, you must call esvect with the appropriate option \(begin{array}{c} before loading mismath. For example, using \usepackage [d] \{esvect}\) will provide the arrows produced by default in [5].

\boldvect

The \vect macro allows vector names to be typeset using bold italic font, as rec-

⁵It will look the same as the one provided by Günter Milde's textalpha package [14].

⁶The definition of most macros in this package, will only take effect if the macro has not been previously defined by another package. This ensures compatibility and avoids conflicts when using the mismath package with other LATPAX packages.

⁷esvect provides the \vv macro used by \vect.

ommended by ISO [2] [3], instead of using arrows. By using the \boldvect command, you can modify the behavior of \vect locally or globally, depending on its placement in the document (inside or outside a group or an environment):

\[\boldvect \vect{v} = \lambda\vect{e}_x+\mu\vect{e}_y. \]
$$v = \lambda e_x + \mu e_y$$
.

\boldvectcommand

By default \boldvect uses the \boldsymbol command⁸ from the amsbsy package, which is automatically loaded by amsmath. However, you may prefer other packages that produce bold italic fonts, such as fixmath with the \mathbold command, isomath with \mathbfit or bm with the \bm command; unicode-math provides the \symbfit command. To use an alternative command instead of \boldsymbol in mismath, redefine \boldvectcommand, for instance after loading fixmath:

\renewcommand\boldvectcommand{\mathbold}.

According to ISO rules, symbols for matrices are also in bold italic. Therefore you can use the same \boldvect command or create another alias.

\arrowvect

At any moment, you can revert to the default behavior using the inverse switch \arrowvect. These switches can be placed anywhere, whether inside mathematical mode or within an environment (with a local effect) or outside (with a global effect).

\hvect

When vectors with arrows are typeset side by side, the arrows can be set up slightly higher using $\$ which places a vertical phantom box containing "t") to avoid inelegant effects. For example, writing

- $\overrightarrow{AB} = \overrightarrow{u} + \overrightarrow{AC}$, obtained with \hvect{u}, is better than $\overrightarrow{AB} = \overrightarrow{u} + \overrightarrow{AC}$;
- $\vec{a} \cdot \vec{b} = 0$, obtained with \hvect{a}, is better thant $\vec{a} \cdot \vec{b} = 0$.

This adjustment ensures a more visually pleasing appearance when vectors with arrows are combined in an equation. The \boldvect and \arrowvect switches have the same effect on \hvect as they do on \vect.

\hvec

In a similar way, \hvec raises the little arrow produced by the \LaTeX command \vec, to the height of the letter "t" (but \boldvect have no effect here):

- $\mathscr{P} = \vec{f} \cdot \vec{v}$, obtained with \hvec{v}, is better than $\mathscr{P} = \vec{f} \cdot \vec{v}$.
- $\vec{f} = m\vec{a}$, obtained with \hvec{a}, is better than $\vec{f} = m\vec{a}$.

\norm

The norm of a vector is conventionally represented using the delimiters \left\end \reft\end \reft\end \right\end{arg} a plus (+) or minus (-) sign follows the opening delimiter) or \left\end{arg} to right\end{arg} to radaptive delimiters. Unfortunately, these delimiters are always vertically centered, relatively to the mathematical center line, whereas vectors with arrows are asymmetric objects. The code $\norm{\vec{h}}\$ raises a smaller double bar to produce $\|\vec{h}\|$ instead of $\|\vec{h}\|$ or $\|\vec{h}\|$. Let's notice that the height of the bars don't adjust to content, but however to context: main text, subscripts or exponents, e.g. $e^{\|\vec{h}\|}$. This macro is useful only for arguments of special height, such as \vec{h} or \overrightarrow{AB} and may give bad results in other situations.

⁸\mathbf produces upright bold font, even when used in combination with \mathit.

\mathbfsfit \tensor

For tensors symbols, ISO rules recommend using sans serif bold italic, but there is no such math alphabet in the default \LaTeX mathematical style. However, the mismath package defines this alphabet (assuming the font encoding and package you use permits it) and provides the macro mathbfsfit or its alias tensor. By using tensor you can produce T.

2.3 Standard operator names

\di The *differential* operator should be typeset in upright shape, not in italics, to distinguish it from variables (as mentioned in [1] [2] [4] [27]). To achieve this, we provide the \di command. Take a look at the following examples (notice the thin spaces before the d, just like with classic function's names):

This command can also represent distance (hence its name):

$$\lambda d(A, \mathcal{F}) + \mu d(B, \mathcal{H}).$$

To refer to probability and expectation the proper use is to typeset the capital letters P, E in roman just like any standard function identifier. This can be achieved with \P and \E commands.

\Par The \P command already existed to refer to the end of paragraph symbol ¶ and has been redefined, but this symbol can still be obtained with \Par.

Variance is generally denoted by var or Var (see table below), but some authors prefer to use V, which can be produced using \V.

\MathProba \MathNormal

\۷

As for e, i or j, you can use \MathUp{P}, \MathUp{E} or \MathUp{V} to avoid typing many \P, \E or \V. However you can also achieve this in a single command with \MathProba, for example \MathProba{P,E}. We get the inverse toggle with \MathIt for any individual letter or \MathNormal for a list.

\probastyle

Some authors use "blackboard bold" font to represent probability, expectation and variance: $\mathbb{P}, \mathbb{E}, \mathbb{V}$. The \probastyle macro sets the appearance of \P, \E and \V. For instance \renewcommand\probastyle{\mathbb}^{10} brings the previous "double-struck" letters. The \mathbb command comes from amsfonts package (loaded by amssymb but also available standalone) which needs to be called in the preamble.

The following standard operator names are defined in mismath:

⁹MT_EX provides also Pr which gives Pr.

¹⁰The effect of this redefinition is global or local to the container environment in which it is used.

\adj	adj	\erf	erf	\Re	Re
\Aut	Aut	\grad	grad	\rot	\overrightarrow{rot}
$\backslash {\tt codim}$	codim	\id	id	\sgn	sgn
\Conv	Conv	\Id	Id	\sinc	sinc
\cov	cov	\im	im	\spa	span
\Cov	Cov	\Im	Im	\tr	tr
\curl	curl	\1b	lb	\var	var
\divg	div	\lcm	lcm	\Var	Var
\End	End	\rank	rank	\Zu	Z

By default, operators returning vectors, \grad and \curl (or its synonym \rot rather used in Europe), are written with an arrow on the top. When \boldvect is activated, they are typeset in bold style: **grad**, **curl**, **rot**. For the variance, the covariance and the identity function, two notations are proposed, with or without a first capital letter, because both are very common. On the other hand, 'im' stands for the image of a linear transformation (like 'ker' for the kernel) whereas 'Im' is the imaginary part of a complex number. Please note that \div already exists (÷) and \span is a TeX primitive; they haven't been redefined. Therefore the provided macros are called \divg (divergence) and \spa (span of a set of vectors). Furthermore \Z is used to denote the set of integers (see 2.4), which is why we used \Zu, to designate the center of a group: Z(G) (from German Zentrum).

\oldRe \oldIm

The \Re and \Im macros already existed to refer to real and imaginary part of a complex number, producing outdated symbols \Re and \Im . However, they have been redefined according to current usage, as mentioned in the above table. Nevertheless, it is still possible to obtain the old symbols with \oldRe and \oldIm.

The package mismath also provides some (inverse) circular or hyperbolic functions, that are missing in \LaTeX :

\arccot	arccot	\arsinh	arsinh	\arcoth	arcoth
\sech	sech	\arcosh	arcosh	\arsech	arsech
\cech	cech	\artanh	artanh	\arcach	arcech

\big0 \bigo \lito Asymptotic comparison operators (in Landau notation) are obtained with \bigO or \bigo and \lito commands:

$$n^2 + \mathcal{O}(n\log n)$$
 or $n^2 + O(n\log n)$ and $e^x = 1 + x + o(x^2)$.

2.4 A few useful aliases

In the tradition of Bourbaki and D. Knuth, proper use requires that classic sets of numbers are typeset in bold roman: R, C, Z, N, Q, whereas "double-barred" or "openwork" letters $(\mathbb{R}, \mathbb{C}, \mathbb{Z}, \ldots)$ are reserved for writing at the blackboard [27]. Similarly, to designate a field we use F or K (Körper in German). We obtain these symbols with the following macros:

$$\R$$
, \C , \Z , \N , \Q , \F , \K .

\mathset

The \mathset command enables you to change the behavior of all these macros in a global way. By default, \mathset is an alias for \mathbf, but if you prefer openwork letters, you can simply place \renewcommand\mathset{\mathbb} where you want, for instance in the preamble after loading the amsfonts package (which provides the "blackboard bold" typeface, also loaded by amssymb).

\onlymathC

The macro \onlymathC is designed for cases when \C is already defined, but only in text mode (usually when loading the Russian language with babel or polyglossia). The macro preserves the original definition for text mode and allows you to use \C for the complex number set in math mode. For this purpose, simply call \onlymathC once in the preamble or anywhere in the document.

\ds The \displaystyle command is very common, so the \ds alias is provided. Not only it eases typing but also it makes source code more readable.

Symbols with limits behave differently for in-line formulas or for displayed equations. In the latter case, "limits" are placed under or above the symbol whereas for in-line math mode, they are placed on the right, as a subscript or exponent. Compare: $\zeta(s) = \sum_{n=1}^{\infty} \frac{1}{n^s}$ with

$$\zeta(s) = \sum_{n=1}^{\infty} \frac{1}{n^s}.$$

\dlim \dsum \dprod \dcup \dcap With in-line math mode, displaymath can be forced with \displaystyle or its alias \ds. However, when using these commands, all the rest of the current mathematical environment will be set in displaymath mode (as shown in the previous example, where the fraction will be expanded). To limit the display style effect to the affected symbol only, similar the the amsmath command \dfrac, we can use the following macros: \dlim, \dsum, \dprod, \dcup, \dcap. So

$$\displaystyle \lim_{x\to \infty} \frac{1}{x}$$
 yields $\displaystyle \lim_{x\to +\infty} \frac{1}{x}$.

\lbar \hlbar Large bars over expressions are obtained with \overline or its alias \lbar, to get for instance $\overline{z_1}\overline{z_2}$. Similar to vectors, you can raise the bar (from the height of "h") with the \hlbar command, to correct uneven bars heights.

$$\overline{z+z'} = \overline{z} + \overline{z'}$$
, obtained with \hlbar{z}, is better than $\overline{z+z'} = \overline{z} + \overline{z'}$.

\eqdef The \eqdef macro writes the equality symbol topped with 'def', or with ' Δ ' for \eqdef* \eqdef* (thanks to the MEX command \stackrel):

$$\begin{array}{ll} \label{eq:theta} & \operatorname{e}^{\mathrm{i}\theta} \overset{\mathrm{def}}{=} \cos\theta + \mathrm{i}\sin\theta \\ \\ \label{eq:theta} & \operatorname{e}^{\mathrm{i}\theta} \overset{\mathrm{def}}{=} \cos\theta + \mathrm{i}\sin\theta \\ \\ \label{eq:theta} & \operatorname{e}^{\mathrm{i}\theta} \overset{\Delta}{=} \cos\theta + \mathrm{i}\sin\theta \\ \\ \label{eq:theta} & \operatorname{e}^{\mathrm{i}\theta} \overset{\Delta}{=} \cos\theta + \mathrm{i}\sin\theta \\ \\ \end{array}$$

\unbr \unbr is an alias for \underbrace¹¹, making source code more compact.

 $^{^{11}}$ The mathtools package by Morten Høgholm and Lars Madsen [8] provides a new and improved version of the \underbrace command, along with many other useful macros. It is loaded by mismath.

$$\label{eq:qapmul} $$ \C (QAP)^n = \mathbb{Q}AP \times QAP \times \cdots \times QAP \times QAP$$

\iif is an alias for "if and only if", to be used in text mode.

2.5 Improved spacing in mathematical formulas

\then The \then macro produces the symbol \Rightarrow surrounded by large spaces just like the \txt standard macro \iff does it with \Rightarrow. Similarly, the \txt, based on the \text macro from the amstext package (loaded by amsmath), leaves em quad spaces (\quad) around the text. See the following example:

\mul The multiplication symbol obtained with \times produces the same spacing as addition or subtraction operators, whereas division obtained with / is closer to its operands. This actually hides the priority of multiplication over + and -. That's why we provide the \mul macro, behaving like / (ordinary symbol) and leaving less space around than \times:

$$\lambda + \alpha \times b - \beta \times c$$
, obtained with \mul, is better than $\lambda + \alpha \times b - \beta \times c$.

When using \mul before a function name or around a \left...\right structure, the space may be too large on one side of \mul. To ensure the same amount of space on both sides of \mul, you can use thin negative spaces \! or enclose the function or structure with braces:

 $x \times \sin x$, obtained with $x \setminus \text{mul}\{\sin x\}$, is slightly better than $x \times \sin x$.

$$\int \frac{\pi}{2} \times \frac{\pi}{2} \times \frac{\pi}{2} \times 2$$
, which is better than $\sin(\frac{\pi}{2}) \times 2$.

The thin negative space after the function name is not relative to $\mbox{\tt mul}$, but is due to the fact that spaces around a $\mbox{\tt left...}$ right structure are bigger than those produced by single parenthesis (...).

\pow In the same way, when typesetting an exponent after a closing big parenthesis produced by \right), the exponent appears to be a little to far from the parenthesis. To address this issue, the \pow{ $\langle expr \rangle$ }-{ $\langle pow \rangle$ } command is provided, which sets $\langle expr \rangle$ between parentheses and adjusts the positioning of the exponent $\langle pow \rangle$ slightly closer to the right parenthesis 12. Compare:

$$e^a \sim \left(1 + \frac{a}{n}\right)^n$$
 which may be better than $e^a \sim \left(1 + \frac{a}{n}\right)^n$.

\abs The correct typesetting of absolute value (or modular for a complex number) is achieved using \lvert ... \rvert, rather than |, as the latter doesn't maintain proper

¹²This macro gives bad results with normal-sized parenthesis.

spacing in some situations (when a sign follows the open delimiter). For bars whose height has to adapt to the content, we can use \left\vert ...\right\vert or, more simply, the \abs{...} command, which is equivalent¹³.

\lfrac

The \lfrac macro behaves like \frac but with thicker spaces around the arguments, making the corresponding fraction bar slightly longer:

$$\begin{array}{ll} \begin{array}{ll} \begin{array}{ll} \begin{array}{ll} \begin{array}{ll} \begin{array}{ll} \begin{array}{ll} \end{array} \end{array} & \overline{Z} = & \overline{z_1 - z_2} \\ \end{array} \\ \begin{array}{ll} \begin{array}{ll} \end{array} & \overline{Z} = & \overline{z_1 - z_2} \end{array} \\ \end{array} \\ \end{array}$$

[ibrackets]

Open intervals are commonly represented with parenthesis, e.g. $(0, +\infty)$, but sometimes square brackets are used, especially in French mathematics: $]0, +\infty[$. In that specific case, the space around the square brackets is often inappropriate, as in the expression $x \in]0, +\infty[$. To address this issue, we have redefined the brackets in the ibrackets package [26]. This one can be optionally 14 loaded by mismath using the ibrackets package option. Thus $x \in [-\infty]$ \cup 14 loaded by $^{$

yields
$$x \in]-\pi,0[\cup]2\pi,3\pi[$$
 with ibrackets, instead of $x \in]-\pi,0[\cup]2\pi,3\pi[$ without ibrackets.

In our code, the symbols [and] are set as 'active' characters, behaving like ordinary characters and not as delimiters in most cases. Therefore, a line break could occur between the two brackets, but it is always possible to transform them into delimiters using \left and \right.

However, when a bracket is *immediately* followed by a + or - character, it becomes an open delimiter. Therefore, when the left bound contains an operator sign, *you don't have to leave a space between the first bracket and the sign*, otherwise, the spaces surrounding the operator will be too large. For example if you write $x \in -\infty$, of instead of $x \in -\infty$, of instance $x \in -\infty$, of instance $x \in -\infty$, of $x \in -\infty$,

Besides, there are other approaches, for example the \interval macro from the interval package [18], or \DeclarePairedDelimiters from the mathtools package [8] (but this command is incompatible with ibrackets).

[decimalcomma]

In many countries, except notably in English-speaking countries, the comma is used as a decimal separator for numbers. However, in the math mode of \LaTeX , the comma is always, by default, treated as a punctuation symbol and therefore is followed by a space. This is appropriate in intervals: $\{[a,b]\}$ results in [a,b], but is not appropriate for numbers where the comma represents the decimal separator. For example, $\{12,5\}$ is displayed as $\{12,5\}$ instead of $\{12,5\}$.

Two very convenient packages allow handling the decimal comma in math mode: icomma by Walter Schmidt [19] and ncccomma by Alexander I. Rozhenko [20]. The second package takes a more generic approach, however it poses several compatibility

¹³We could also define \abs using \DeclarePairedDelimiter from the mathtools package [8].

¹⁴This functionality is optional because there is a conflict when using another command for open intervals with square brackets defined by \DeclarePairedDelimiter from mathtools [8].

issues, in particular when running through Lual*TeX, using unicode-math and calling \setmathfont. Therefore we propose the decimalcomma package [21], functionally identical to that of ncccomma but with lighter code and without the aforementioned incompatibility. It can be loaded by mismath using the decimalcomma package option¹⁵.

2.6 Environments for systems of equations and small matrices

The system environment, defined in the mismath package, is used to represent a system of equations:

\systemsep

This first example could also have been achieved using the cases environment from the amsmath package, although cases places mathematical expressions closer to the bracket. The \systemsep length allows you to adjust the gap between the bracket and the expressions. By default, the gap is set to \medspace. You can reduce this gap by redefining the command, e.g.: \renewcommand{\systemsep}{\thinspace}. Alternatively you can increase the gap using \thickspace and the same spacing as of the cases environment is obtained with \renewcommand\systemsep}{}. The \systemsep command allows for greater flexibility in adjusting the spacing within the system environment.

 $system[\langle coldef \rangle]$

By default, a system is written like an array environment with only one column, left aligned. However the system environment has an optional argument that allows to create systems with multiple columns, specifying their alignment using the same syntax as the array environment in ETeX. For instance, using \begin{system}[c1] will produce a two-column system, with the first column centered and the second column left-aligned, as shown in the following example:

\systemstretch

The default spacing between the lines of a system environment has been slightly enlarged compared to the one used in array environments (using a factor of 1.2). This can be adjusted by using \renewcommand{\systemstretch}-{ $\langle stretch \rangle$ }, where $\langle stretch \rangle$ is the desired value for the spacing. You can place this command inside the current mathematical environment for a local change, or outside for a global change. The default value for is 1.2. Furthermore you can also use the end of the line with a spacing option, as demonstrated above with \\[1ex], to control the spacing between specific lines in the system.

 $^{^{15}}$ ibrackets and decimal comma are the only options specific to the mismath package.

Another example with \begin{system}[rl@{\quad}1] 16:

$$\begin{cases} x + 3y + 5z = 0 & R_1 \\ 2x + 2y - z = 3 & R_2 \iff \begin{cases} x + 3y + 5z = 0 & R_1 \\ 4y + 11z = 3 & R_2 \leftarrow 2R_1 - R_2 \\ 5y + 7z = -1 & R_3 \leftarrow \frac{1}{2}(3R_1 - R_3) \end{cases}$$

Let's also mention the systeme package [22] which provides a lighter syntax and automatic alignments for linear systems. Additionally, there is the spalign package [23], which offers a convenient and easy syntax for systems and matrices with visually appealing alignments.

spmatrix

The amsmath package offers several environments to typeset matrices: For example, the pmatrix environment surrounds the matrix with parenthesis, and the smallmatrix environment creates a smaller matrix suitable for insertion within a text line. We provide a combination of the these both functionalities with the spmatrix environment: $\$ vec{u}\begin{spmatrix}-1\2\end{spmatrix} yielding \vec{u} ($^{-1}$).

The mathtools package enhances the amsmath matrix environments and also provides a small matrix environment with parenthesis: psmallmatrix. Moreover, with the starred version \begin{psmallmatrix*}[\langle col\rangle], you can choose the alignment inside the columns (c, 1 or r). However, the space before the left parenthesis is unfortunately too narrow compared to the space inside the parenthesis. To illustrate this, consider the following comparison: $\vec{u} {-1 \choose 2}$ (using mismath's spmatrix) vs. $\vec{u} {-1 \choose 2}$ (using mathtools psmallmatrix).

For typesetting various kinds of matrices, let's mention the excellent nicematrix package by François Pantigny [24].

2.7 Displaymath in double columns

mathcols

The mathcols environment allows you to arrange "long" calculations in double columns, separated with a central rule, as shown in the following example. However, to use this feature, the multicol package must be loaded in the preamble. The mathcols environment activates mathematical mode in display style and uses an aligned environment.

$$\frac{1}{2 \times \left(\frac{1}{4}\right)^n + 1} \ge 0.999$$

$$\iff 1 \ge 1.998 \left(\frac{1}{4}\right)^n + 0.999$$

$$\iff n \ge \frac{\ln(1998)}{\ln 4} \approx 5.4$$

$$\iff 0.001 \ge \frac{1.998}{4^n}$$

$$\iff n \ge 6$$

\changecol

The \changecol macro is used to switch to the next column, and alignments within the columns is done using the classic delimiters &, to separate entries, and \\, to start a new row.

 $^{^{16}}$ **Q**{...} sets inter-column space.

2.8 Old commands

Here is a summary table of old commands that were used until version 2.2. These commands are still functional and will be maintained for the time being, but a warning message indicates the new alternative. They used to work only in the preamble, affecting the entire document globally, and lacked an inverse switch. These old commands can now be replaced by the more versatile and powerful \MathUp macro, which can be used anywhere in the document or preamble and has an inverse switch \MathIt.

Old command	New alternative
\enumber	\MathUp{e}
\inumber	\MathUp{i}
\jnumber	\MathUp{j}
\PEupright	\MathProba{PE}

You can also utilize \MathNumbers instead of \MathUp with an argument containing all the constants you want to be typeset in roman (among 'e, i, j').

Additionally you can include V in the argument of \mathbb{P}^{P} to refer to variance, (or even use \mathbb{P}^{P} MathUp(E)).

In version 2.3 we attempted to replace these old commands with package options based on keyval. However, we found that this method was less efficient and have decided to abandon it. As a result, the command \mismathset is now obsolete. Additionally, the command, \paren, which was used before version 2.0, is no longer supported.

3 Implementation

We load certain packages conditionally to avoid 'option clash' errors in cases where these packages have been previously loaded with other options.

```
1\newif\ifmm@ibrackets % initialized to false
2\newif\ifmm@decimalcomma
3\DeclareOption{ibrackets}{\mm@ibracketstrue}
4\DeclareOption{decimalcomma}{\mm@decimalcommatrue}
5\DeclareOption*{\PassOptionsToPackage{\CurrentOption}{amsmath}}
```

```
6\ProcessOptions \relax
7\@ifpackageloaded{amsmath}{}{\RequirePackage{amsmath}}
8\@ifpackageloaded{mathtools}{}{\RequirePackage{mathtools}}
9\@ifpackageloaded{esvect}{}{\RequirePackage[b]{esvect}}
10\RequirePackage{ifthen}
11\RequirePackage{xparse} % provides \NewDocumentCommand, now in LaTeX3
12\RequirePackage{xspace}
13\RequirePackage{iftex}
14\RequirePackage{etoolbox} % provides \AtEndPreamble
15\RequirePackage{xkeyval}
```

The package unicode-math causes some compatibility issues with the options ibrackets or decimalcomma: the respective packages must be loaded *after* unicodemath, but mismath (like amsmath) must be loaded *before* unicode-math. And to complicate matters, unicode-math defines all its commands by \AtBeginDocument. Therefore we used the command \AtBeginDocument within \AtEndPreamble (from the etoolbox package).

Moreover the command \mathbfsfit (used for tensors) is already defined in unicode-math and will not be redefined if unicode-math is loaded.

```
17 \newif\ifmm@unicodemath
18 \newif\ifmm@multicol
19 \AtEndPreamble{% necessary to work with unicode-math
      \@ifpackageloaded{multicol}{\mm@multicoltrue}{\mm@multicolfalse}
20
      \@ifpackageloaded{unicode-math}{\mm@unicodemathtrue}{
21
          \mm@unicodemathfalse
22
          \DeclareMathAlphabet{\mathbfsfit}{\encodingdefault}%
23
              {\sfdefault}{bx}{it}}
24
      \AtBeginDocument{% necessary to work with unicode-math
25
          \ifmm@ibrackets\RequirePackage{ibrackets}\fi
26
27
          \ifmm@decimalcomma\RequirePackage{decimalcomma}\fi
      }
28
29 }
30
```

\bslash

The \bslash macro originates from Frank Mittelbach's doc.sty package. It can be employed in other documents as an alternative to \textbackslash, especially in situations where \textbackslash does not work correctly, such as inside warning messages.

```
31 {\catcode'\|=\z@ \catcode'\\=12 |gdef|bslash{\}} % \bslash command 32
```

\mm@warning \mm@macro \mm@operator The next three internal macros serve as meta commands for conditionally defining macros while providing a warning message if the macro already exists. These macros can be useful in other packages as well.

```
36 }
37 \newcommand\mm@macro[2]{
      \@ifundefined{#1}{
38
          \expandafter\def\csname #1\endcsname{#2}
39
40
      }{\mm@warning{#1}}
41 }
42 \NewDocumentCommand\mm@operator{O{#3}mm}{%
43
      \@ifundefined{#1}{
          \DeclareMathOperator{#2}{#3}
44
      }{\mm@warning{#1}}
45
46 }
47
```

To produce the correct upright shape font when working with the beamer package, you don't have to use \mathrm but rather \mathup (based on \operatorfont from the amsopn package). This command also works fine with other sans serif fonts like cmbright.

Moreover for beamer, which changes the default font family (to sans serif), \e, \i, \j have no effect without \AtBeginDocument. \AtBeginDocument is also necessary to redefine \i when calling the hyperref package which overwrites the \i definition.

```
48 \@ifundefined{mathup}{
49 \providecommand*{\mathup}[1]{{\operatorfont #1}}
50 \right\{\mathup\} \right\} \right\{\mathup\} \right\{\mathup\} \right\{\mathup\} \right\{\mathup\} \right\} \right\{\mathup\} \right\{\mathup\} \right\{\mathup\} \right\} \right\{\mathup\} \right\{\mathup\} \right\{\mathup\} \right\} \right\{\mathup\} \right\{\mathup\} \right\{\mathup\} \right\{\mathup\} \right\} \right\{\mathup\} \right\{\mat
```

\MathFamily

The following macros \MathUp and \MathIt are switches that transform any chosen letter in math mode to roman or italic style. These switches can be used anywhere in the document or preamble. They are based on the generic macro \MathFamily. To obtain a letter in roman style instead of italic, we need to change the mathcode digit that represents the font family: 1 to 0.

For example, except for Lua \LaTeX , mathcode of the 'e' letter is: 'e="7165 (decimal 29029), with the second digit '1' indicating "italic" style. To get a roman 'e', we need to change its mathcode to "7065.

When used in the preamble, we call \MathFamily by \AtBeginDocument for working with the beamer package. Let's notice that \MathFamily has an erratic behavior when unicode-math is loaded, but fortunately, in that case, the \DeclareMathSymbol can be used instead, even outside the preamble.

With a similar approach we could also create additional macros to set any letter in bold or sans serif. However, there is no default family number associated with these typefaces. The family number depends on the font package being loaded and may vary depending on specific \DeclareSymbolFont used. Therefore, setting letters in bold or sans serif requires additional consideration and may not have a straightforward solution.

In addition to \MathUp and \MathIt, we also offer the following two commands to set a group of letters in roman typeface: one for for mathematical constants, among 'e, i, j', and the other for probability operators, among or 'P, E, V'.

```
127 \newcommand*\MathNumbers[1] {%
       \in0{e}{\#1} \subset \MathUp{e} \fi
128
       \in O{i}{\#1} \in O{i}{\#1} \fi
129
       \left( \frac{1}{41} \right) \
130
131 }
132
133 \newcommand*\MathProba[1]{%
       \in (P){\#1} \subset \mathbb{P}{\#1} 
134
       \in@{E}{#1} \ifin@ \MathUp{E} \fi
135
       \in0{V}{\#1} \subset \MathUp{V} \fi
136
137 }
138
```

\apply With the inverse switch \MathNormal, you can apply the normal (italic) style on any comma-separated list of characters. This is achieved using the \apply macro, e.g. \apply\macro{arg1,arg2} expands to \macro{arg1}\macro{arg2}. Thus \apply\MathUp{e,i,j} is equivalent to \MathUp{e}\MathUp{i}\MathUp{j}. I discovered this powerfull macro on iterate190.rssing.com by searching for "TeX How to iterate over a comma separated list". The answer was posted under the pseudonym 'wipet' on 2021/02/26. Let its author, Petr Olšák, be thanked. This macro allows to accomplish tasks that usual loop instructions like \@for or \foreach cannot achieve due to errors like "! Improper alphabetic constant". For instance, if you try \def\letter{A} \MathUp{\letter} it will fail because the control sequence \letter is not strictly equivalent here to the single character 'A'.

```
139 \def\apply#1#2{\apply@#1#2,\apply@,}
140 \def\apply@#1#2,{\ifx\apply@#2\empty
141 \else #1{#2}\afterfi@{\apply@#1}\fi}
142 \def\afterfi@#1#2\fi{\fi#1}
143
144 \newcommand*\MathNormal[1]{% list argument
145 \apply\MathIt{#1}
146}
```

The following commands were used until version 2.2 but still work. They were intended to set some letters in upright shape in math mode, but only worked in the preamble. This is now managed by the more powerful \MathUp command, and the old commands are maintained for compatibility reasons.

```
148 \newcommand{\enumber}{%
       \PackageWarning{mismath}{Old command \string\enumber\space
149
           is used. \MessageBreak

           It can be replaced by \string\MathProba{PE}}
169
       \MathUp{P}\MathUp{E}
170
171 }
172
```

Obtaining an upright Greek letter π must be handled differently. The switches are called $\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\protect\$

But \pinumber must be called first in the preamble with an optional argument. This argument can be a valid command name that produces an upright pi letter (after having loading an appropriate package). When given without an argument in the preamble, \pinumber uses an LGR font encoding called lmr. A new feature (v2.11) is to use \pinumber with a keyval option to use many other Greek pi letters without loading a whole package, thus without altering the other (italic) Greek letters. We achieve

this with \DeclareSymbolFont and \DeclareMathSymbol. We just have to know the "name" of the desired symbol font. Compatibility with unicode-math is a bit tricky!

```

And finally we present the remaining macros.

With Cyrillic languages, the command \C may already be defined (only for text mode). Thus, it will not be redefined by mismath. However, one may still want to use our \C macro only for math mode without interfering the definition of the text \C, therefore the \onlymathC macro.

```
388 \mm@macro{mathset}{\mathbf}
