Abstract

This package defines and implements the data type bit set, a vector of bits. The size of the vector may grow dynamically. Individual bits can be manipulated.

1.1 Introduction

Annotations in the PDF format know entries whose values are integers. This numbers are interpreted as set of flags specifying properties. For example, annotation dictionaries can have a key `/F`. The bits of its integer value are interpreted the following way:

Bit position	Property name
1	Invisible
2	Hidden
3	Print
4	NoZoom
5	NoRotate
6	NoView
7	ReadOnly
...	...

Now, let's see how these values are set in package `hyperref` before it uses this package (before v6.77a):

```
\ifFld@hidden /F 6\else /F 4\fi
```

Where are the other flags? The following example for key `/Ff` in a widget annotation supports at least three properties:

```
\ifFld@multiline
  \ifFld@readonly /Ff 4097\else /Ff 4096\fi
\else
  \ifFld@password
    \ifFld@readonly /Ff 8193\else /Ff 8192\fi
  \else
    \ifFld@readonly /Ff 1\fi
  \fi
\fi
```

But you see the point. It would be a nightmare to continue this way in supporting the missing flag settings. This kind of integers may have up to 32 bits.

Therefore I wanted a data structure for setting and clearing individual bits. Also it should provide an export as decimal number. The snipsets above are executed in expansion contexts without `LATEX`'s stomach commands. It would be convenient to have an expandable conversion from the data structure to the integer that gets written to the PDF file.

This package `bitset` implements such a data structure. The interface is quite close to Java's class `BitSet` in order not to learn too many interfaces for the same kind of data structure.

1.2 Glossary

Bit set: A bit set is a vector of bits or flags. The vector size is unlimited and grows dynamically. An undefined bit set is treated as bit set where all bits are cleared.

Bit sets are addressed by name. A name should consist of letters or digits. Technically it must survive `\csname`, see `LATEX`'s environment names for other names with such a constraint. Package `babel`'s shorthands are not supported due to technical reasons. Shorthand support would break expandable operations.

Size: A size of a bit set is the number of bits in use. It's the number of the highest index, incremented by one. Sizes are in the range 0 up to 2147483647, the highest number supported by `LATEX`.

Index: Bit positions in a bit set are addressed by an index number. The bit vector is zero based. The first and least significant bit is addressed by index 0 and the highest possible bit by 2147483646.

Bit: A bit is encoded as 0 for cleared/disabled or 1 for set/enabled.

1.3 Design principles

Name conventions: To avoid conflicts with existing macro names, the operations are prefixed by the package name.

Zero based indexes: The first bit is addressed by zero. (Convention of array indexing in C, Java, ...)

Unlimited size: There is no restriction on the size of a bit set other than usual memory limitations. `\bitsetSetDec` and `\bitsetGetDec` transparently switch to package `bignumcalc` if the numbers get too large for `TeX`'s number limit.

Expandability: Any operation that does not change the bit set is expandable. And all operations that extract or calculate some result do this in exactly two expansion steps. For example, a macro `\Macro` wants a bit set as decimal number. But the argument must be a plain number without macros. Thus you could prefix `\bitsetGetDec` with `\number`. However this won't work for bit sets with 31 or more bits because of `TeX`'s number limit of $2^{31} - 1$. then just hit the operator with two `\expandafter`:

```
\expandafter\expandafter\expandafter  
\Macro\bitsetGetDec{foo}
```

`\bitsetGetDec` is hit first by the third `\expandafter` and then by the second one.

Format independence: This package is written as `LATEX` package, but it does not depend on `LATEX`. It will also work for other formats such as plain `TeX`.

Independence from `TeX` engines: Vanilla `TeX` is all you need. Calculations are delegated to packages `intcalc` and `bignumcalc`. They don't need any special features, but they will switch to a little more efficient implementation if features such as `\numexpr` are available.

Numeric arguments: Anything that is accepted by `\number`. If ε -`TeX` is detected, also expressions for `\numexpr` are supported. The only exception so far is the number for `\bitsetSetDec`. The number might be too large for `\number` or `\numexpr`.

Error messages: In expandable contexts, only a limited set of `TeX` primitive commands work as expected. So called stomach commands behave like `\relax` and don't get expanded or executed. Unhappily also the error commands belong to this category. The expandable operations will throw an unknown control sequence instead to get `TeX`'s and user's attention. The name of these control sequences starts with `\BitsetError:` with the type of error after the colon.

^bMacros are expandable.

1.5 Package loading

The package can be used as normal L^AT_EX package:

```
\usepackage{bitset}
```

Also plain T_EX is supported:

```
\input bitset.sty\relax
```

1.6 Operators

The following macros work on and with bit sets. A bit set $\langle BitSet \rangle$ is represented by a name. The should consist of letters and digits. Technically it must survive \csname. It is the same constraint that must be satisfied by label or environment names in L^AT_EX.

However active characters that are shorthands of package babel are not supported. Support for shorthands works by an assignment. But many operators such

as `\bitsetGetDec` must be usable in expandable contexts. There assignments will not be executed in the best case or they will cause errors.

The bits in a bit set are addressed by non-negative integers starting from zero. Thus negative index numbers cause an error message. Because index numbers are TEX numbers. The largest index is 2147483647. But in practice memory limits and patience limits will be very likely reached much before.

1.6.1 Miscellaneous

There isn't a separate operation for bit set creation. For simplicity an undefined bit set is treated as bit set with all bits cleared.

```
\bitsetReset {\langle BitSet\rangle}
```

Macro `\bitsetReset` clears all bits. The result is an empty bit set. It may also be used as replacement for an operation “new”, because an undefined bit set is defined afterwards.

```
\bitsetLet {\langle BitSet A\rangle} {\langle BitSet B\rangle}
```

Macro `\bitsetLet` performs a simple assignment similar to TEX's `\let`. After the operation $\langle \text{BitSet } A \rangle$ has the same value as $\langle \text{BitSet } B \rangle$. If $\langle \text{BitSet } B \rangle$ is undefined, then $\langle \text{BitSet } A \rangle$ will be the empty bit set.

Note: If $\langle \text{BitSet } A \rangle$ exists, it will be overwritten.

1.6.2 Import

```
\bitsetSetBin {\langle BitSet\rangle} {\langle BinaryNumber\rangle}
\bitsetSetOct {\langle BitSet\rangle} {\langle OctalNumber\rangle}
\bitsetSetHex {\langle BitSet\rangle} {\langle HexadecimalNumber\rangle}
```

The numbers are interpreted as bit vectors and the flags in the bit $\langle \text{BitSet} \rangle$ set are set accordingly. These numeric arguments are the only arguments where spaces are allowed. Then the numbers are easier to read.

```
\bitsetSetDec {\langle BitSet\rangle} {\langle DecimalNumber\rangle}
```

Macro `\bitsetSetDec` uses $\langle \text{DecimalNumber} \rangle$ to set the bit set $\langle \text{BitSet} \rangle$. The numeric argument must expand to a plain number consisting of decimal digits without command tokens or spaces. Internally this argument is expanded only. It cannot be passed to `\number` or `\numexpr`, because the number may be too large for them. However `\number` or `\the\numexpr` may be used explicitly. This also helps for unexpandable number command tokens or registers (`\z@`, `\cne`, `\count@`, ...). Also IATEX' `\value` needs prefixing:

```
\bitsetSetDec{foo}{\number\value{bar}}
```

1.6.3 Export

```
\bitsetGetBin {\langle BitSet\rangle} {\langle MinSize\rangle}
\bitsetGetOct {\langle BitSet\rangle} {\langle MinSize\rangle}
\bitsetGetHex {\langle BitSet\rangle} {\langle MinSize\rangle}
```

These macros returns the bit set as binary, octal or hexadecimal number. If the bit size is smaller than $\langle \text{MinSize} \rangle$ the gap is filled with leading zeros. Example:

```
\bitsetReset{abc}
\bitsetSet{abc}{2}
\bitsetGetBin{abc}{8} → 00000100
\bitsetSet{abc}{5}\bitsetSet{abc}{7}
\bitsetGetHex{abc}{16} → 00A2
```

Macro `\bitsetGetHex` uses the uppercase letters A to F. The catcode of the letters is one of 11 (letter) or 12 (other).

`\bitsetGetDec {⟨BitSet⟩}`

Macro `\bitsetGetDec` returns the bit set `⟨BitSet⟩` as decimal number. The returned number can be larger than TeX's number limit of $2^{31} - 1$.

1.6.4 Logical operators

`\bitsetAnd {⟨BitSet A⟩} {⟨BitSet B⟩}`

$A_{\text{new}} := A_{\text{old}}$ and B (\forall bits)

`\bitsetAndNot {⟨BitSet A⟩} {⟨BitSet B⟩}`

$A_{\text{new}} := A_{\text{old}}$ and (not B) (\forall bits)

`\bitsetOr {⟨BitSet A⟩} {⟨BitSet B⟩}`

$A_{\text{new}} := A_{\text{old}}$ or B (\forall bits)

`\bitsetXor {⟨BitSet A⟩} {⟨BitSet B⟩}`

$A_{\text{new}} := A_{\text{old}}$ xor B (\forall bits)

1.6.5 Shifting

`\bitsetShiftLeft {⟨BitSet⟩} {⟨ShiftAmount⟩}`
`\bitsetShiftRight {⟨BitSet⟩} {⟨ShiftAmount⟩}`

A left shift by one is a multiplication by two, thus left shifting moves the flags to higher positions. The new created low positions are filled by zeros.

A right shift is the opposite, dividing by two, moving the bits to lower positions. The number will become smaller, the lowest bits are lost.

If the `⟨ShiftAmount⟩` is negative, it reverts the meaning of the shift operation. A left shift becomes a right shift. A `⟨ShiftAmount⟩` of zero is ignored.

1.6.6 Bit manipulation

`\bitsetClear {⟨BitSet⟩} {⟨Index⟩}`
`\bitsetSet {⟨BitSet⟩} {⟨Index⟩}`
`\bitsetFlip {⟨BitSet⟩} {⟨Index⟩}`

This macros manipulate a single bit in `⟨BitSet⟩` addressed by `⟨Index⟩`. Macro `\bitsetClear` disables the bit, `\bitsetSet` enables it and `\bitsetFlip` reverts the current setting of the bit.

```
\bitsetSetValue {\langle BitSet\rangle} {\langle Index\rangle} {\langle Bit\rangle}
```

Macro `\bitsetSetValue` puts bit $\langle Bit \rangle$ at position $\langle Index \rangle$ in bit set $\langle BitSet \rangle$. $\langle Bit \rangle$ must be a valid TeX number equals to zero (disabled/cleared) or one (enabled/set).

1.6.7 Bit retrieval

```
\bitsetGet {\langle BitSet\rangle} {\langle Index\rangle}
```

Macro `\bitsetGet` extracts the status of the bit at position $\langle Index \rangle$ in bit set $\langle BitSet \rangle$. Digit 1 is returned if the bit is set/enabled. If the bit is cleared/disabled and in cases of an undefined bitset or an index number out of range the return value is 0.

```
\bitsetNextClearBit {\langle BitSet\rangle} {\langle Index\rangle}
```

Starting at position $\langle Index \rangle$ (inclusive) the bits are inspected. The first position without a set bit is returned. Possible results are decimal numbers: $\langle Index \rangle$, $\langle Index \rangle + 1$, ..., (∞)

```
\bitsetNextSetBit {\langle BitSet\rangle} {\langle Index\rangle}
```

Starting at position $\langle Index \rangle$ (inclusive) the bits are inspected and the index position of the first found set bit is returned. If there isn't such a bit, then the result is -1. In summary possible results are decimal numbers: -1, $\langle Index \rangle$, $\langle Index \rangle + 1$, ..., (∞)

```
\bitsetGetSetBitList {\langle BitSet\rangle}
```

Macro `\bitsetGetSetBitList` is an application for `\bitsetNextSetBit`. The set bits are iterated and returned as comma separated list of index positions in increasing order. The list is empty in case of an empty bit set.

1.6.8 Bit set properties

```
\bitsetSize {\langle BitSet\rangle}
```

Macro `\bitsetSize` returns number of bits in use. It is the same as the index number of the highest set/enabled bit incremented by one.

```
\bitsetCardinality {\langle BitSet\rangle}
```

Macro `\bitsetCardinality` counts the number of set/enabled bits.

1.6.9 Queries

Also the query procedures are expandable. They ask for a piece of information about a bit set and execute code depending on the answer.

```
\bitsetIsDefined {\langle BitSet\rangle} {\langle Then\rangle} {\langle Else\rangle}
```

If the bit set with the name $\langle BitSet \rangle$ exists the code given in $\langle Then \rangle$ is executed, otherwise $\langle Else \rangle$ is used.

```
\bitsetIsEmpty {\langle BitSet\rangle} {\langle Then\rangle} {\langle Else\rangle}
```

If the bit set $\langle BitSet \rangle$ exists and at least one bit is set/enabled, the code in $\langle Then \rangle$ is executed, $\langle Else \rangle$ otherwise.

```
\bitsetEquals {\langle BitSet A\rangle} {\langle BitSet B\rangle} {\langle Then\rangle} {\langle Else\rangle}
```

Both bit sets are equal if and only if either both are undefined or both are defined and represents the same bit values at the same positions. Thus this definition is reflexive, symmetric, and transitive, enough for an equivalent relation.

```
\bitsetIntersects {\langle BitSet A\rangle} {\langle BitSet B\rangle} {\langle Then\rangle} {\langle Else\rangle}
```

If and only if $\langle BitSet A \rangle$ and $\langle BitSet B \rangle$ have at least one bit at the same position that is set, then code part $\langle Then \rangle$ is executed.

```
\bitsetQuery {\langle BitSet\rangle} {\langle Index\rangle} {\langle Then\rangle} {\langle Else\rangle}
```

It's just a wrapper for `\bitsetGet`. If the bit at position $\langle Index \rangle$ is enabled, code $\langle Then \rangle$ is called.

2 Implementation

The internal format of a bit set is quite simple, a sequence of digits 0 and 1. The least significant bit is left. A bit set without any flag set is encoded by 0. Also undefined bit sets are treated that way. After the highest bit that is set there are no further zeroes. A regular expression of valid bit sets values:

$0|[01]*1$

4 Installation

4.1 Download

Package. This package is available on CTAN¹:

[CTAN:macros/latex/contrib/oberdiek/bitset.dtx](http://ctan.org/pkg/bitset) The source file.

[CTAN:macros/latex/contrib/oberdiek/bitset.pdf](http://ctan.org/pkg/bitset) Documentation.

Bundle. All the packages of the bundle ‘oberdiek’ are also available in a TDS compliant ZIP archive. There the packages are already unpacked and the documentation files are generated. The files and directories obey the TDS standard.

[CTAN:install/macros/latex/contrib/oberdiek.tds.zip](http://ctan.org/pkg/oberdiek.tds.zip)

TDS refers to the standard “A Directory Structure for TeX Files” ([CTAN:tds](http://ctan.org/pkg/tds)/[tds.pdf](http://ctan.org/pkg/tds.pdf)). Directories with `texmf` in their name are usually organized this way.

4.2 Bundle installation

Unpacking. Unpack the `oberdiek.tds.zip` in the TDS tree (also known as `texmf` tree) of your choice. Example (linux):

```
unzip oberdiek.tds.zip -d ~/texmf
```

¹<http://ctan.org/pkg/bitset>

Script installation. Check the directory `TDS:scripts/oberdiek/` for scripts that need further installation steps. Package `attachfile2` comes with the Perl script `pdfatfi.pl` that should be installed in such a way that it can be called as `pdfatfi`. Example (linux):

```
chmod +x scripts/oberdiek/pdfatfi.pl
cp scripts/oberdiek/pdfatfi.pl /usr/local/bin/
```

4.3 Package installation

Unpacking. The `.dtx` file is a self-extracting `docstrip` archive. The files are extracted by running the `.dtx` through plain `TeX`:

```
tex bitset.dtx
```

TDS. Now the different files must be moved into the different directories in your installation TDS tree (also known as `texmf` tree):

bitset.sty	→ tex/generic/oberdiek/bitset.sty
bitset.pdf	→ doc/latex/oberdiek/bitset.pdf
test/bitset-test1.tex	→ doc/latex/oberdiek/test/bitset-test1.tex
test/bitset-test2.tex	→ doc/latex/oberdiek/test/bitset-test2.tex
test/bitset-test3.tex	→ doc/latex/oberdiek/test/bitset-test3.tex
bitset.dtx	→ source/latex/oberdiek/bitset.dtx

If you have a `docstrip.cfg` that configures and enables `docstrip`'s TDS installing feature, then some files can already be in the right place, see the documentation of `docstrip`.

4.4 Refresh file name databases

If your `TeX` distribution (`teTeX`, `mikTeX`, ...) relies on file name databases, you must refresh these. For example, `teTeX` users run `texhash` or `mktexlsr`.

4.5 Some details for the interested

Unpacking with L^AT_EX. The `.dtx` chooses its action depending on the format:

plain TeX: Run `docstrip` and extract the files.

L^AT_EX: Generate the documentation.

If you insist on using L^AT_EX for `docstrip` (really, `docstrip` does not need L^AT_EX), then inform the autodetect routine about your intention:

```
latex \let\install=y\input{bitset.dtx}
```

Do not forget to quote the argument according to the demands of your shell.

Generating the documentation. You can use both the `.dtx` or the `.drv` to generate the documentation. The process can be configured by the configuration file `ltxdoc.cfg`. For instance, put this line into this file, if you want to have A4 as paper format:

```
\PassOptionsToClass{a4paper}{article}
```

An example follows how to generate the documentation with pdfL^AT_EX:

```
pdflatex bitset.dtx
makeindex -s gind.ist bitset.idx
pdflatex bitset.dtx
makeindex -s gind.ist bitset.idx
pdflatex bitset.dtx
```
